Purpose: This template provides a series of scripts to render a markdown document into an interactive website and a series of PDFs.

Internals: GitHub actions and a series of python scrippts. The markdown is handled with pandoc.

Motivation: It makes collaborating on text with GitHub easier, and means that we never need to think about the output.

This work is released by its authors under a CC-BY 4.0 license

Last revision: *February 27, 2023*

1 This template turns README files hosted in a GitHub repo into a formatted manuscript. In practice,
2 this involves converting the README file into various LaTeX files, an interactive website, and an
3 OpenDocument text file (for use in Word).

4 The workflow is *entirely* GitHub-based, and so the manuscript file is contained entirely in the README. There
5 are a few differences with “normal” markdown (or with GFM, the most commonly used variant). First, because
6 manuscripts require extensive metadata, the metadata are stored in a JSON file, which is described in detailed in
7 the Appendix 1. Did we mention this system handles supplementary material? It does. On the website, the
8 appendix are listed at the very bottom of the page, just after the references and before the institutions.

9 The *actual* typesetting logic is handled by another repository, which is located at
10 <https://github.com/PoisotLab/manuscript-typesetter>. If you don’t feel like running foreign code on your
11 repo, you are absolutely right. This is why the GitHub action file associated to this template will specify which
12 release will be downloaded, and so you can inspect what the typesetting steps are doing. In short: they convert
13 the bibliography into a CSL JSON, reformat the metadata so they are usable with pandoc templates, download
14 a whole bunch of binaries to do the typesetting (as well as the TeX Gyre fonts we use for text, and the
15 JuliaMono font we use for code), and then return everything as a compressed file, which is then deployed using
16 GitHub pages.

17 The core bit of configuration is the `metadata.json` file, which handles information about authorship,
18 affiliations, the abstract, keywords, etc. All documents will be deployed to gh-pages *only* on push events from
19 the main branch. All of the artifacts will be built when doing pull requests, so you can check that merging a
20 branch is *not* going to cause the compilation of the documents to fail; indeed, you can download the artifacts
21 produced during the run, to check the PDF and html files. The website is only updated from the main branch.

22 Deploying the template

23 The process of deploying this template has been *greatly* streamlined from previous versions:

- 24 • Click on the “Use this template” button, making sure to check the option to import all branches (this will
25 import gh-pages and allow deploys to start immediately)
- 26 • Edit `README.md` with your own text, commit, and push

- This push will trigger the first build - the builds are only active on the main branch (*not* master!), and on pull requests
- Go to <http://you.github.io/repo-name/> to view the html version, and get access to the PDFs
- Add your references to the `references.bib` file
- Edit the `metadata.json` file to add the title, abstract, authors

In particular, note that *you do not need* to create a personal access token to deploy to gh-pages (from where the website is served).

The metadata file

General information

The title is a field in the `metadata.json`:

```
{  
  "title": "Preprint template"  
}
```

Authorship

Authors are listed as objects in the `authors` block. Each author is specified as follows:

```
{  
  "familyname": "Bob",  
  "givennames": "Alice",  
  "email": "alice.bob@u.edu",  
  "orcid": "0000-0000-0000-0001",  
  "affiliations": [  
    "Affiliation 1",  
    "Affiliation 2"  
  ],  
}
```

```
"status": ["corresponding", "equal"]
}
```

39 The email field is recommended for all authors. The status field is only useful for the corresponding author,
40 and to denote equal contributions. These informations are rendered on the initial page. If an orcid is given, it
41 will be linked on the HTML and PDF versions.

42 Note that there is *no need* to number the affiliations - a small python script will take care of this automatically.

43 Abstract

44 This template supports three types of abstracts, indicated in the metadata file as abstract:

45 A regular abstract is defined as

```
"abstract": "A very long string"
```

46 An itemized abstract is an array of strings, each representing a bullet point:

```
"abstract": [
  "Point 1",
  "Point 2"
]
```

47 A structured abstract is an object with key-value pairs :

```
"abstract": {
  "Location": "Worldwide",
  "Organisms": "Mammals"
}
```

48 Citation style

49 The citationstyle key corresponds to the name, with .cs1 ommited, of a CSL stylesheet stored in the [citation](#)
50 [style language](#) repository. Note that there is no difference between main and dependent styles, the build engine

51 will take the correct steps to get the correct style. The default is "citationstyle": "ecology-letters".
52 There is a longer section about references management later on.

53 **References management**

54 The references are managed by pandoc. Note that we *do not* use pandoc-citeproc, which was an external
55 module for older pandoc versions. References *must* be stored in a references.bib file, and that it would make
56 sense to order it alphabetically by key.

57 We use [Zotero](#) for references management, and for the lab's manuscripts, we work from folders in a shared
58 library (with a folder for every manuscript).

59 It is recommended to use the [Better BibTeX](#) plugin for citation key generations, and auto-export of the shared
60 library to the references.bib file. We use a citation key format meant to convey information on the author
61 (first author full name), date (complete year), and title (first three letters of the first two non-stop words). It must
62 be set in the Better BibTeX preferences as (you might need to remove the line changes):

```
63 auth.fold.fold + year + title.fold.nopunctordash.skipwords.lower.select(1,1).capitalize()
```

64 It is a good idea to configure Better BibTeX to auto-export on change, and to remove a lot of fields that are not
65 strictly speaking required for references. The list of fields we usually ignore is:

```
66 abstract,copyright,annotation,file,pmid,month,shorttitle,keywords
```

67 The citations are done using the normal markdown syntax, where @Elton1927AniEco produces Elton (1927),
68 and [@Camerano1880EquViv] produces (Camerano 1880).

69 **Figures, Tables, and other floats**

70 Note that you can wrap the text of legends for both figures and tables. This avoids the issue of having very long
71 lines.

72 Mathematics

73 The following equation

$$J'(p) = \frac{1}{\log(S)} \times \left(- \sum p \times \log(p) \right) \quad (1)$$

74 is produced using

```
$$J'(p) = \frac{1}{\text{log}(S)} \times \dots $$ {#eq:eq1}
```

75 and can be referenced using @eq:eq1, which will result in eq. 1. Note that because we use pandoc-crossref,
76 the label “eq.” will be generated automatically.

77 Tables

78 Table legends go on the line after the table itself. To generate a reference to the table, use {#tbl:id} – then, in
79 the text, you can use {@tbl:id} to refer to the table. For example, the table below is tbl. 1. You can remove the
80 *table* in front by using !@tbl:id, or force it to be capitalized with *tbl:id.

Table 1: This is a table, and its identifier is id – we can refer to it using {@tbl:id}. Note that even if the table legend is written below the table itself, it will appear on top in the PDF document.

Sepal.Length	Sepal.Width	Petal.Length	Petal.Width	Species
5.1	3.5	1.4	0.2	setosa
5.0	3.6	1.4	0.2	setosa
5.4	3.9	1.7	0.4	setosa

81 Figures

82 Figures can have a legend – all figures *must* be in the figures/ folder of the project, as it is also used for the
83 website. We recommend to use good resolution images, rather than PDFs, or at least to have multiple versions
84 available.

85 ![This is the legend of the figure...](figures/figure.png){#fig:figure}

86 [Figure 1 about here.]

87 We can now use @fig:figure to refer to fig. 1.

88 **Example text**

89 Connectance, defined as the ratio of realized interactions on the total number of potential interactions, is one of
90 the most common descriptor of network structure. In a bipartite network with T species at the top, and B at the
91 bottom, having a total of L interactions, it is defined as $Co = L/(T \times B)$. Connectance has a lower bound, as the
92 network cannot have fewer interactions than the number of species in its more speciose level – the minimal
93 connectance is therefore $c_m = \max(T, B)$. This makes the connectance of networks of different sizes difficult to
94 compare, especially since bipartite networks tends to have a low connectance. For this reason, we used a
95 corrected version of connectance, defined as

$$Co^* = \frac{L - c_m}{T \times B - c_m}. \quad (2)$$

96 **This is a subsection**

97 This takes values between 0 (the network has the minimal number of interactions) and 1 (all species are
98 connected), but is robust to variations in species richness.

99 **This is another subsection**

100 This takes values between 0 (the network has the minimal number of interactions) and 1 (all species are
101 connected), but is robust to variations in species richness.

102 **Some non-standard maths**

103 The phylogenetic reconstruction of $\hat{\mathcal{L}}$ and $\hat{\mathcal{H}}$ has an associated uncertainty, represented by the breadth of the
104 uniform distribution associated to each of their entries. Therefore, we can use this information to assemble a

105 probabilistic metaweb in the sense of (Poisot2016StrPro?), i.e. in which every interaction is represented as a
106 single, independent, Bernoulli event of probability p .

107 Specifically, we have adopted the following approach. For every entry in $\hat{\mathcal{L}}$ and $\hat{\mathcal{R}}$, we draw a value from its
108 distribution. This results in one instance of the possible left ($\hat{\ell}$) and right (\hat{r}) subspaces for the Canadian
109 metaweb. These can be multiplied, to produce one matrix of real values. Because the entries in $\hat{\ell}$ and \hat{r} are in
110 the same space where \mathcal{L} and \mathcal{R} were originally predicted, it follows that the threshold ρ estimated for the
111 European metaweb also applies. We use this information to produce one random Canadian metaweb,
112 $N = \hat{\mathcal{L}}\hat{\mathcal{R}}' \geq \rho$.

113 Because the intervals around some trait values can be broad (in fact, probably broader than what they would
114 actually be), we repeat the above process 2×10^5 times, which results in a probabilistic metaweb P , where the
115 probability of an interaction (here conveying our degree of trust that it exists given the inferred trait
116 distributions) is given by the number of times where it appears across all random draws N , divided by the
117 number of samples. An interaction with $P_{i,j} = 1$ means that these two species were predicted to interact in all
118 2×10^5 random draws, etc..

119 Things to know

120 The text can use unicode: for example, this α is written as is in the main text. The previous sentence is written as

The text can use unicode: for example, this α is written as is in the main text.

121 and so yes, you *can* actually use unicode in code blocks as well.
